

KINGDOM

FAIR DEAL PROTOCOL

Version 0.1

Core doctrine

Not everything valuable must be charged, but everything valuable should be visible.

A non-commission, energy-first protocol for fair negotiation, transparent agreements, transaction memory, and verified benevolent contribution.

Project: STVcentral's Kingdom Infrastructure

Status: Working constitutional specification — settled decisions plus implementation blueprint

Date: July 14, 2026

Current human coefficient: $H_i = 625$ (unchanged)

Purpose of this document

To convert the day's conceptual decisions into a stable, auditable foundation that can guide the calculator, the AI negotiation layer, the ledger, reputation, and a future MVP.

12	Core data model
13	Safeguards and non-goals
14	Settled decisions and open questions

Interpretation rule

This document distinguishes settled rules from proposals. “Settled” means accepted in the design discussion. “Open” means intentionally left for later validation.

EXECUTIVE VIEW

1. Protocol in one page

Kingdom Infrastructure is a non-commission transaction and negotiation system that helps people recognize, discuss, and exchange visible and unseen value fairly. Its public interface is conversational AI; its mathematical foundation is the auditable KingdomWatt engine.

The platform helps parties form a deal, records what they agreed to, and remembers how the transaction ended. It does not enforce the deal, judge guilt, or become a private court.

The three layers

Layer	Purpose	Primary output
KingdomWatt kernel	Deterministic energy-based measurement and presets.	Auditable values, assumptions, confidence, and allocation.
Fair-AI negotiation	Private advocates plus a neutral mediator.	Mutually intelligible deal options and a consent-ready agreement.
Ledger and reputation	Records agreed terms and transaction outcomes.	Transaction history, benevolent contribution, and unhappy-transaction context.

The decisive distinctions

Benevolent contribution = agreed full value – agreed settlement

The value knowingly released without equivalent settlement.

Unfulfilled obligation = agreed settlement – delivered settlement

A broken or incomplete promise; never reclassified as generosity.

Energy first

Every primary number is expressed in KingdomWatts. Currency is only one possible settlement medium and may be shown through an explicit bridge; it never defines the underlying value.

2. Constitutional principles

Principle	Rule
Visibility before price	Not everything valuable must be charged, but everything valuable should be visible.
Energy before currency	Value is measured from human energy, presence, resources, risk, and contribution—not from the currency amount offered.
Price is not value	A CAD \$200 deal may activate far more value without making the performance “worth only \$200.”
Consent over coercion	The AI proposes and explains. Humans accept, reject, or revise. The platform does not bind them autonomously.
Record, do not enforce	The platform records agreements and outcomes but does not collect debts, decide guilt, or impose obedience.
Transaction-gated reputation	Only verified parties to an actual transaction may affect that transaction’s reputation record.
No five-star theatre	Reputation is factual transaction history, not popularity, fan voting, or a compressed moral score.
Generosity is visible	The agreed gap between full value and settlement is automatically recorded as benevolent contribution.

Principle	Rule
Broken promises stay broken	Undelivered agreed settlement is an unfulfilled obligation, not a retroactive contribution.
No commission incentive	The platform does not profit by taking a percentage of the value exchanged and therefore should not optimize for higher deal prices merely to increase its own revenue.
Auditability	Formulas, presets, assumptions, allocations, and confidence must be explainable and reviewable.
Currency creation tabled	Benevolent contribution is non-spendable recognition. It does not mint KWK or automatically create advertising credit.

3. System architecture

3.1 KingdomWatt kernel

The existing calculator remains the educational and audit interface. Its formulas and presets become callable services beneath the AI. The current website human coefficient stays at $H_i = 625$ unless a future validated decision explicitly changes it.

- Accept structured inputs for people, time, energy, presence, equipment, materials, travel, risk, reusable preparation, and external settlement.
- Return energy values in KWK with the contributing components visible.
- Preserve preset versions so later rule changes do not rewrite historical agreements.
- Distinguish direct delivered value, reusable value activated, transaction expenses, and embedded capacity.
- Never allow a language model to silently replace deterministic calculations.

3.2 Fair-AI layer

The public user should not have to understand coefficients. They describe the exchange in ordinary language. The AI asks only the missing questions, maps the answers to the kernel, and explains the result.

Agent	Duty	Privacy boundary
Party A advocate	Clarify goals, contributions, limits, and acceptable structures.	Private limits stay private unless the party authorizes disclosure.
Party B advocate	Clarify budget, resources, risks, needs, and non-cash offers.	Private limits stay private unless the party authorizes disclosure.
Neutral mediator	Compare authorized facts and propose understandable agreements.	Sees only shared facts and permitted negotiation ranges.

3.3 Ledger and reputation

Only mutually agreed terms enter the ledger as the official transaction. The ledger then records delivery, settlement, completion, revision, cancellation, dispute, or resolution without claiming authority to enforce.

4. Energy-first value model

KingdomWatts are the unit of accounting. Currency, goods, services, access, food, transportation, footage, revenue share, and other benefits are settlement media whose value is translated into energy terms for the agreement.

4.1 Core value categories

Category	Definition
Direct delivered value	Work and value delivered specifically in the transaction: performance, setup, service time, production, transport, administration.
Transaction expenses	Fuel, parking, materials, rentals, permits, consumables, and other out-of-pocket inputs.

Category	Definition
Equipment deployment	Use, wear, risk, transport, and energy consumption of tools and equipment.
Reusable preparation	Rehearsals, arrangements, templates, software, set design, or preparation that can serve more than one transaction.
Embedded capacity	Skill, repertoire, trust, reputation, audience, systems, and accumulated ability activated in the exchange.
Risk and constraints	Cancellation exposure, exclusivity, damage exposure, timing scarcity, uncertainty, or opportunity cost.
Settlement received	All concrete value promised in return, expressed in energy equivalents.
Benevolent contribution	The mutually agreed value provided beyond the mutually agreed settlement.

4.2 Currency bridge

A currency amount may be displayed for practical settlement, but the transaction stores both the original amount and the energy bridge used at agreement time. Later bridge changes must not rewrite historical records.

Required display order

Show KWK first. Show currency only as an optional settlement translation: “2,500 KWK, settled as approximately CAD \$200 using the agreed bridge.”

5. Invoice mode and full-value mode

Mode	Question answered	Includes
Invoice mode	What immediate settlement is reasonable for this deal?	Direct work, expenses, deployment, risk, and a justified allocation of reusable preparation.
Full-value mode	What total value is being activated or transferred?	Invoice components plus embedded and reusable value that may not be fully chargeable to one buyer.

The two modes prevent a common error: treating every valuable input as though it must be invoiced fully to the present buyer. Rehearsal is valuable, but a reusable set may serve many shows. Full-value mode reveals it; invoice mode allocates it reasonably.

Interpretive example

A one-hour show may have a CAD \$200 settlement, a 6,000 KWK invoice estimate, and a 10,000 KWK full-value record. All three can be true simultaneously.

6. Transaction lifecycle and ledger

Stage	Function
Describe	Each party describes the exchange, goals, constraints, and contributions.
Clarify	Advocates ask only the missing questions and flag assumptions.
Measure	The kernel produces invoice-mode and full-value estimates in KWK.
Negotiate	The mediator proposes deal structures without revealing private limits.
Agree	Both parties approve the shared terms, valuations, settlement, obligations, and permissions.
Record	The signed-off agreement becomes the immutable transaction version.
Deliver	The parties perform their obligations outside the platform's

Stage	Function
	coercive control.
Confirm outcome	Each party records delivery, satisfaction, revision, cancellation, dispute, or resolution.
Update history	The ledger updates benevolent contribution and transaction-based reputation facts.

6.1 Ledger equations

$$B = \max(0, V_{\text{agreed}} - S_{\text{agreed}})$$

B = benevolent contribution; V = mutually agreed full value; S = mutually agreed settlement.

$$U = \max(0, S_{\text{agreed}} - S_{\text{delivered}})$$

U = unfulfilled obligation. It remains separate from benevolent contribution.

$$\text{Completed settlement ratio} = S_{\text{delivered}} \div S_{\text{agreed}}$$

Used as transaction context, not as a universal moral score.

6.2 Statuses

Status	Meaning
Draft	Private and editable; no reputation impact.
Proposed	Shared for review; no reputation impact.
Agreed	Mutually accepted; official terms recorded.
In progress	Delivery period has started.
Completed	Agreed delivery and settlement confirmed.
Completed with unhappiness	Completed, but at least one party reports an unsatisfactory outcome.
Unresolved	A material part of delivery or settlement remains contested or incomplete.
Resolved after disagreement	The parties later acknowledge a workable resolution.
Cancelled by agreement	Both parties accepted cancellation terms.

7. Benevolent contribution

Because only mutually agreed terms enter the ledger, an agreed gap between full value and settlement is voluntary by definition. It does not require a second donation step after completion.

Settled rule

Agreed value minus agreed settlement is automatically recorded as a benevolent contribution to the world.

7.1 Properties

- Non-spendable and non-transferable.
- Does not create new KWK.
- Does not automatically create advertising credit, ranking priority, or other guaranteed economic privilege.
- Transaction-backed and traceable to the agreement that produced it.
- Publicly visible only according to the contributor's chosen profile privacy settings.

- Shown separately from unsettled, disputed, or unfulfilled amounts.
- May be displayed as lifetime total, recent total, category breakdown, and transaction count.

7.2 Why recognition is enough

A large verified benevolent-contribution number can be a meaningful form of status for people proud of what they have given. Keeping it non-spendable protects the signal: the recognition itself is the reward, not a disguised route to currency creation or platform advantage.

8. Reputation without ratings

Reputation is not open commentary and not a five-star score. It is a factual summary of the person's verified transaction history.

8.1 Who may affect reputation

Hard gate

Only a verified party listed in the on-platform transaction may affect that transaction's reputation outcome. Fans, followers, competitors, outsiders, and mobs have no rating power.

Content-safety reporting may remain a separate moderation function, but it must never alter transactional reputation unless the reporter was an actual party to the deal.

8.2 Public reputation fields

Field	Example	Interpretation
Completed transactions	147	Volume of completed agreements.
Transactions marked unhappy	6	At least one participant reported unhappiness.
Lifetime unhappy rate	4.1%	Contextualizes the raw count.
Currently unresolved	1	Transactions still lacking a mutually acknowledged resolution.
Resolved after disagreement	4	Shows repair, not merely conflict.
Recent unhappy rate	1.2%	Provides recency without erasing history.

8.3 No guilt verdict

The platform does not label a participant guilty, innocent, victim, complainer, difficult, or trustworthy. It shows what happened procedurally: a real transaction existed, one or both parties were unhappy, and the matter is resolved or unresolved.

9. Fair-AI negotiation room

9.1 User experience

A common user begins with a natural-language description rather than a calculator form. Example: "We are a five-person band playing one hour. The venue can pay \$200. We bring our gear, drive separately, and expect about sixty people."

The AI identifies unseen components, asks concise clarifying questions, and returns a deal map in KWK. The user can inspect the assumptions, revise them, or open the full calculator.

9.2 Mediator output

- Shared facts and assumptions.
- Invoice-mode estimate and full-value estimate in KWK.
- Agreed settlement options, including concrete non-cash value.

- Benevolent contribution implied by each option.
- Obligations, deadlines, permissions, rights, cancellation terms, and risk allocation.
- A plain-language fairness explanation and uncertainty statement.
- Accept, reject, or revise controls for each party.

9.3 AI limits

- May infer ordinary missing structure, but must label assumptions.
- May not disclose a party's private minimum, maximum, or motive without permission.
- May not claim that a deal is objectively fair merely because both parties accepted it.
- May not present vague "exposure" as settlement without concrete deliverables.
- May not alter the formula or coefficient silently.
- May not create or spend currency.
- May not enforce the agreement or decide guilt.

10. Band-show worked example

Scenario: five musicians—two guitarists, one drummer, one bassist, and one lead singer—play a one-hour local show. The venue offers CAD \$200. The band brings equipment and each member spends approximately CAD \$30 on fuel. Exact values below are illustrative until the final preset is calibrated.

10.1 Example value map

Component	Illustrative KWK	Notes
Direct performance and event labour	5,600	Performance, setup, teardown, coordination.
Travel and fuel	1,500	Human travel plus external fuel settlement translated into energy.
Equipment deployment	600	Amplifiers, pedals, instruments, transport, and wear.
Reusable preparation activated	2,300	Repertoire and rehearsal value visible in full-value mode.
Full agreed value	10,000	Illustrative mutually accepted full-value figure.
Agreed settlement	2,500	Equivalent of CAD \$200 at the selected agreement bridge.
Benevolent contribution	7,500	Automatically recorded because it was knowingly agreed.

10.2 Outcome variations

Outcome	Ledger result
Venue delivers the full agreed settlement	Transaction completed; 7,500 KWK benevolent contribution recorded.
Venue promised 2,500 KWK but delivers only 1,500	1,000 KWK unfulfilled obligation; benevolent contribution remains 7,500, not 8,500.
Band and venue revise the deal before performance	A new agreement version is accepted; only the latest accepted terms govern.
A fan dislikes the band and tries to rate them	No effect: the fan was not a transaction party.

11. MVP scope and build sequence

Phase 1 — Protocol and kernel contract

1. Finalize the value ontology and formula vocabulary.
2. Define preset versioning and confidence rules.
3. Expose the existing calculator as a deterministic internal service without changing $H_i = 625$.

4. Implement invoice mode, full-value mode, benevolent contribution, and unfulfilled obligation.

Phase 2 — Single-party Fair Deal Interview

5. Natural-language intake.
6. AI-generated question list.
7. Value map and assumptions.
8. Invoice and full-value views.
9. Draft agreement export.

Phase 3 — Two-party Deal Room

10. Private advocate for each party.
11. Shared facts and selective disclosure.
12. Mediator-generated options.
13. Dual consent and agreement versioning.
14. Ledger creation.

Phase 4 — Outcome and reputation

15. Delivery and settlement confirmation.
16. Unhappy and unresolved states.
17. Resolution updates.
18. Transaction-gated reputation profile.
19. Benevolent-contribution profile totals.

Recommended first coded prototype

One user describes a deal; the system produces an energy-first value map, two modes, an agreement draft, benevolent contribution, and unfulfilled-obligation fields. Two-party negotiation can follow once the core semantics are stable.

12. Core data model

The companion JSON file delivered with this document contains a machine-readable v0.1 schema. The following table summarizes the essential records.

Record	Role
ProtocolVersion	Formula version, coefficient version, preset versions, and constitutional rule version.
Party	Verified identity, display settings, private negotiation settings, and authorization boundaries.
Transaction	Parties, purpose, timestamps, current status, and version history.
ValueComponent	Category, contributor, quantity, energy, presence, confidence, reuse allocation, and evidence.
Valuation	Invoice value, full value, assumptions, uncertainty, and approval state.
SettlementTerm	Settlement medium, amount in native units, agreed KWK equivalent, due conditions, and permissions.
Obligation	Who promises what, to whom, by when, and how completion is acknowledged.
AgreementVersion	Immutable accepted snapshot of facts, values, settlement, obligations, and disclosures.
Outcome	Delivered value, delivered settlement, satisfaction flags, unresolved items, and resolution history.
ReputationSummary	Completed, unhappy, unresolved, resolved, and recent/lifetime rates.
BenevolentContribution	Transaction-backed non-spendable difference between agreed value and agreed settlement.

13. Safeguards and non-goals

13.1 Safeguards

- No reputation effect without a verified transaction relationship.
- No public accusation text required for an unhappy marker.
- Mutual agreement required before terms enter the official ledger.
- Every accepted agreement keeps an immutable version snapshot.
- Every AI inference is distinguishable from a human-provided fact.
- Every currency translation stores the bridge and timestamp used.
- Benevolent contribution cannot be spent, transferred, or converted automatically.
- Unfulfilled obligations cannot be reclassified as benevolence.
- The platform should disclose related-party and repetitive transaction patterns when context is relevant, without declaring fraud.
- Moderation reports remain separate from transactional reputation.

13.2 Explicit non-goals

- Becoming a court, police service, debt collector, or compulsory arbitration authority.
- Producing a universal moral score.
- Making every unequal exchange impossible.
- Forcing users to charge the maximum recognizable value.
- Replacing human consent with AI authority.
- Creating KWK from two-party valuation gaps.
- Rewarding benevolent totals with automatic advertising or financial privileges in v0.1.

14. Settled decisions and open questions

14.1 Settled in v0.1

- The calculator remains the auditable kernel; conversational AI becomes the main public interface.
- Invoice mode and full-value mode are both required.
- All primary values are energy-first and expressed in KWK.
- Currency is an optional settlement bridge, not the basis of value.
- The platform records agreements but does not enforce them.
- Only verified transaction parties can affect reputation.
- Reputation uses unhappy/unresolved/resolved transaction facts, not stars and not guilt labels.
- Only agreed terms enter the ledger.
- Agreed value minus agreed settlement is automatically recorded as benevolent contribution.
- Agreed settlement minus delivered settlement is an unfulfilled obligation.
- Benevolent contribution is non-spendable and does not mint KWK.
- Currency creation and automatic advertising rewards are tabled.
- H_i remains 625 in the current calculator.

14.2 Open for later validation

- Exact band, venue, freelance, product, and community-service presets.
- How reusable preparation is allocated across expected uses.
- How equipment deployment and depreciation are translated into energy consistently.
- Which identity verification level is required for different transaction sizes.
- How much public transaction context accompanies benevolent totals.
- Whether parties may choose private, pseudonymous, or public contribution display.
- How cancellation, force majeure, partial delivery, and amended agreements affect outcome statuses.
- Legal wording, privacy compliance, and jurisdiction-specific agreement notices.
- The sustainable non-commission funding model for operating the infrastructure.

Next materialization target

Convert this protocol into an interactive single-party Fair Deal Interview prototype backed by the companion JSON schema and the existing KingdomWatt kernel.
